

Programming Paradigms: An Introduction

Summer Semester 2023
Dr. Abhishek Tiwari, Prof. Dr. Christian Hammer

What would be the o/p?

```
#include <stdio.h>
```

```
int main(){  
    int buffer[4] = {0,1,2,3};  
    int *ptr = buffer;  
    printf("%d\n", buffer[1]);  
    printf("%d\n", *(ptr+2));  
}
```

```
int buffer[4] = {0,1,2,3};  
int *ptr;
```

```
ptr = buffer;
```

```
buffer = ptr;
```

What does it mean?

```
#include <stdio.h>
```

```
int main(){  
    char *name = "hello world";  
    printf("%c\n", *&*name);  
}
```

What would be the o/p?

- The *syntax* of a programming language is a precise description of all its **grammatically correct** programs
- Precise syntax was first used with Algol 60 and has been used ever since
- Three levels:
 - Lexical Syntax
 - Concrete Syntax
 - Abstract Syntax

- Lexical Syntax — all **basic** symbols of the language
 - names, values, operators, etc.
- Concrete Syntax — **rules** for writing expressions, statements, and programs
- Abstract Syntax — **internal representation** of the program, favoring content over form
 - C: *if(expr) ... discard()*
 - Ada: *if(expr) then discard **then***

- **Similar** to the grammar used in **natural language**
- Defines the structure of a language
 - Michael goes to the park, vs
 - Goes the to Michel park, vs
 - The park goes to Michael
 - Similarly, in C — `int x = 5;` vs `5 int = x;`
- Enables the users of the language to communicate clearly

- A metalanguage — A language used to **define other languages**
- Grammar — a metalanguage used to define the syntax of a language
- Can be formally defined as — $\langle N, T, S, P \rangle$
 - N denotes nonterminal symbols
 - T denotes terminal symbols
 - S denotes the start symbol $S \in N$
 - P denotes a set of production rules for the Grammar

- These are **not** part of the language — used to represent the structure of a language
- For a **natural** language — noun, pronoun, adverb, ...
- For the programming languages — statement, loop, condition, numbers, ...

- **Tokens** of the programming languages
 - keywords, identifiers, operators, e.g., while, for, ...

- Rules to create a grammar
- Defines nonterminal as a series of terminals or nonterminal
 - e.g., $word \rightarrow letter \mid word$

- Multiple approaches to express Grammar
- Backus-Naur form (BNF) — Context-free grammar
- Extended BNF
- Augmented BNF
- Regular grammar
- ...

- Stylized version of a **context-free grammar**
- Sometimes called Backus Normal form
- First used to define syntax of Algol 60
- Defines syntax of major programming languages

- Terminals are written as is, i.e., int, if, for, ...
- Nonterminals are denoted in angled bracket, i.e., $\langle Numbers \rangle$
- Production rules are written as:
 - $\langle nonterminals \rangle ::= \langle terminals \rangle \langle nonterminals \rangle | \langle terminals \rangle \langle nonterminals \rangle \dots$
 - $|$ represents or
 - e.g., $\langle Name \rangle ::= \langle suffix \rangle \langle Last\ Name \rangle ", " \langle First\ Name \rangle | \langle suffix \rangle \langle First\ Name \rangle ", " \langle Last\ Name \rangle$

- Binary digits:
 - $\langle \text{binaryDigit} \rangle ::= 0 \mid 1$
- Defining integers
 - $\langle \text{digit} \rangle ::= 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7 \mid 8 \mid 9$
 - $\langle \text{integer} \rangle ::= \langle \text{digit} \rangle \mid \langle \text{integer} \rangle \langle \text{digit} \rangle$
- Postal Address¹:

$\langle \text{postal-address} \rangle ::= \langle \text{name-part} \rangle \langle \text{street-address} \rangle \langle \text{zip-part} \rangle$

$\langle \text{name-part} \rangle ::= \langle \text{personal-part} \rangle \langle \text{last-name} \rangle \langle \text{opt-suffix-part} \rangle \langle \text{EOL} \rangle \mid \langle \text{personal-part} \rangle \langle \text{name-part} \rangle$

$\langle \text{personal-part} \rangle ::= \langle \text{initial} \rangle "." \mid \langle \text{first-name} \rangle$

$\langle \text{street-address} \rangle ::= \langle \text{house-num} \rangle \langle \text{street-name} \rangle \langle \text{opt-apt-num} \rangle \langle \text{EOL} \rangle$

$\langle \text{zip-part} \rangle ::= \langle \text{town-name} \rangle ", " \langle \text{state-code} \rangle \langle \text{ZIP-code} \rangle \langle \text{EOL} \rangle$

$\langle \text{opt-suffix-part} \rangle ::= "Sr." \mid "Jr." \mid \langle \text{roman-numeral} \rangle \mid ""$

$\langle \text{opt-apt-num} \rangle ::= \langle \text{apt-num} \rangle \mid ""$

1. https://en.wikipedia.org/wiki/Backus%E2%80%93Naur_form

Example: A mini domain specific language

$$\begin{aligned} s \in Stmt & ::= D \mid v = e \mid \mathbf{allocate}(p, c) \mid \mathbf{free}(p) \mid \\ & \quad \mathbf{arraystore}(arr, i, v) \mid \mathbf{arrayload}(arr, i, v) \mid \mathbf{input}(x) \mid \\ & \quad \mathbf{if}(e) \{ \vec{s}_1 \} \mathbf{else} \{ \vec{s}_2 \} \mid \mathbf{while}(e) \{ \vec{s} \} \mid v_n = \mathbf{func}(\vec{v}) \mid \\ & \quad s_1; s_2 \mid \mathbf{skip} \\ e \in Exp & ::= v \mid c \mid v_1 \odot v_2 \mid p \pm c \mid *p \\ D \in Decl & ::= T \mathbf{var} \mid T \mathbf{arr}[n] \mid T *p \end{aligned}$$

$v \in \text{variable}, c \in \text{Constants}, arr \in \text{Arrays}, T \in \text{Type}$

- Consider the grammar for Integer
 - $\langle \text{digit} \rangle ::= 0 \mid 1 \mid 2 \mid 3 \mid 4 \mid 5 \mid 6 \mid 7 \mid 8 \mid 9$
 - $\langle \text{integer} \rangle ::= \langle \text{digit} \rangle \mid \langle \text{integer} \rangle \langle \text{digit} \rangle$
- Let's derive an integer 352 from this grammar

- Process starts with:
 - $\langle \text{Integer} \rangle$
- Use a grammar rule to enable each step:
 - $\langle \text{integer} \rangle ::= \langle \text{digit} \rangle \mid \langle \text{integer} \rangle \langle \text{digit} \rangle$
- Replace a nonterminal by a right-hand side of its (one of) rule
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle \langle \text{digit} \rangle$
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle 2$
- Repeat the above steps
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle \langle \text{digit} \rangle$
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle 2$
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle \langle \text{digit} \rangle 2$
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle 52$
 - $\langle \text{integer} \rangle ::= \langle \text{digit} \rangle 52$
 - $\langle \text{integer} \rangle ::= 352$
- Process is finished when there are only terminal symbols remain

- Derive 352
 - $\langle \text{integer} \rangle ::= \langle \text{integer} \rangle \langle \text{digit} \rangle$
 - $::= \langle \text{integer} \rangle \langle \text{digit} \rangle \langle \text{digit} \rangle$
 - $::= \langle \text{digit} \rangle \langle \text{digit} \rangle \langle \text{digit} \rangle$
 - $::= 3 \langle \text{digit} \rangle \langle \text{digit} \rangle$
 - $::= 35 \langle \text{digit} \rangle$
 - $::= 352$
- The process is called a **leftmost** derivation

- $\text{Integer} \Rightarrow^* 352$ means 352 can be derived in a **finite** number of steps using the grammar for Integer
- $352 \in L(G)$ means 352 is a member of the language defined by Grammar G
- $L(G) = \{ w \in T^* \mid \text{Integer} \Rightarrow^* w \}$ — language defined by grammar G is the set of all symbol string w that can be derived as an Integer

- Aims to show relations between the elements and the grammar
- A parse tree is a graphical representation of a derivation
 - Each internal node of the tree corresponds to a step in the derivation
 - Each child of a node represents a right-hand side of a production
 - Each leaf node represents a symbol of the derived string, reading from left to right

- The step $\langle \text{Integer} \rangle ::= \langle \text{Integer} \rangle \langle \text{digit} \rangle$ appears in a parse tree as:

Parse Tree for 352 as an Integer

- Grammar for the language if arithmetic expression with 1 digit integers, addition, and subtraction
 - $\langle \text{Expr} \rangle ::= \langle \text{Expr} \rangle + \langle \text{Term} \rangle \mid \langle \text{Expr} \rangle - \langle \text{Term} \rangle \mid \text{Term}$
 - $\text{Term} ::= 0 \mid 1 \mid \dots \mid 9$
- Draw parse tree of 5-4+3

Parse Tree of 5-4+3

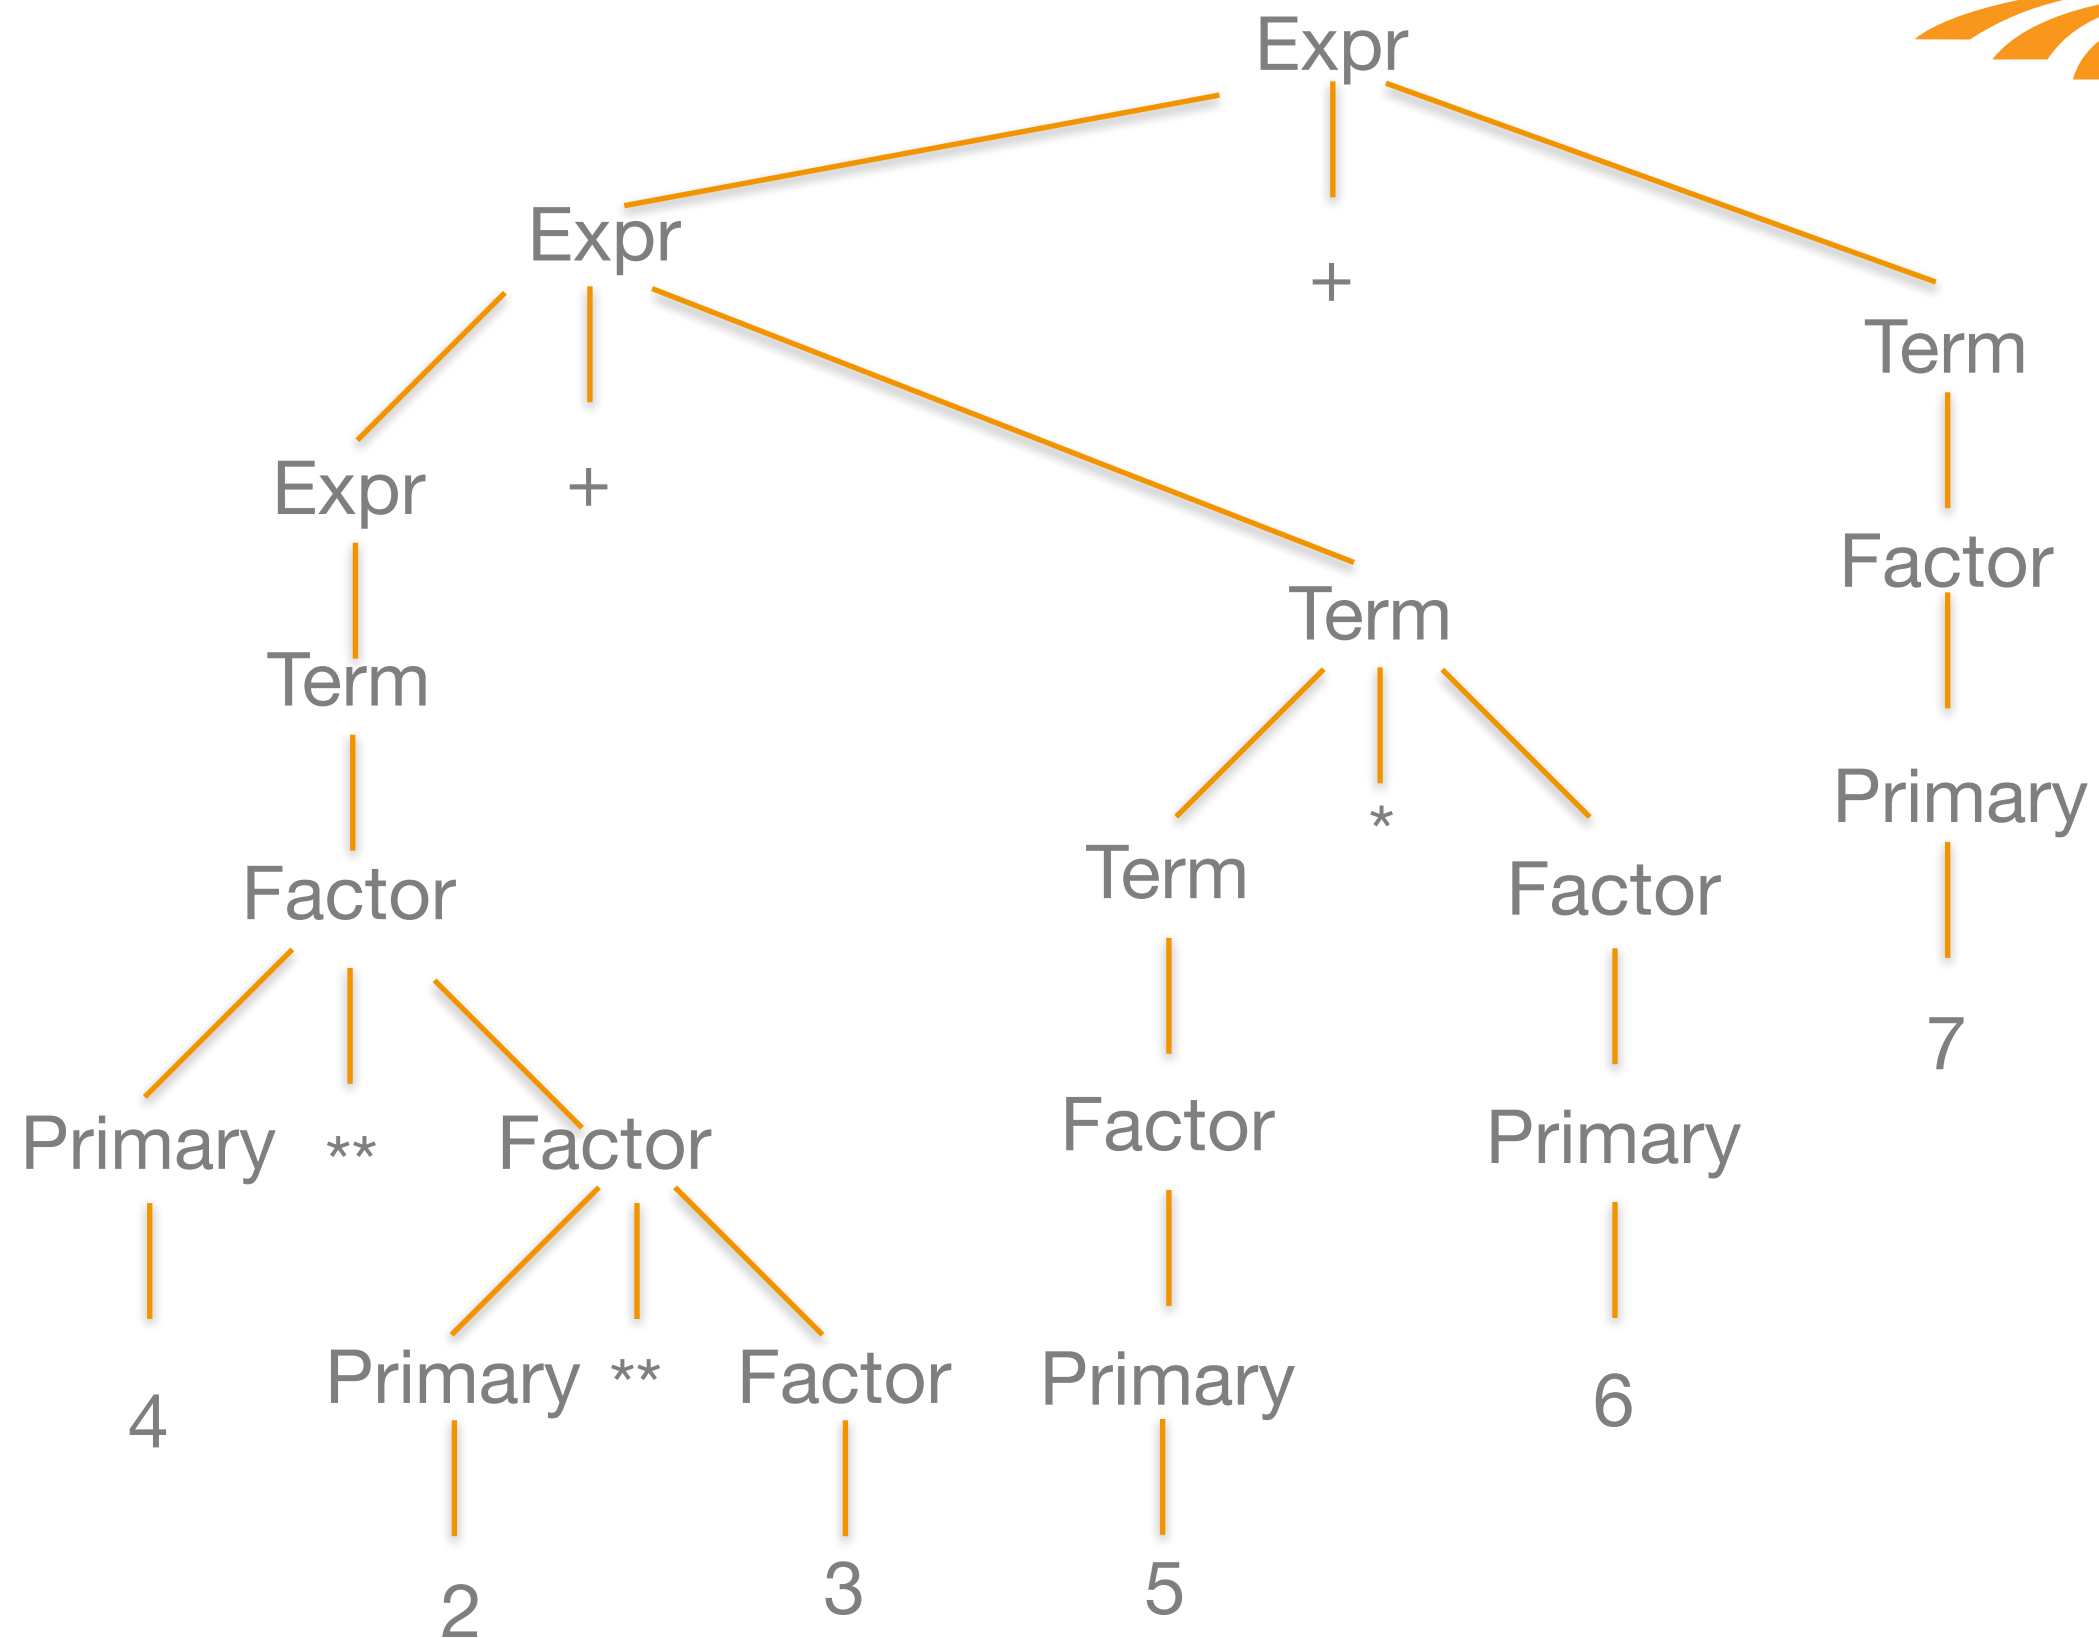

- A grammar can define **associativity** and **precedence** among the operators in an expression
 - e.g., + and — are left-associative operators in math and
 - * and / have higher precedence than + and —
- Consider a Grammar G_1 :
 - $\langle \text{Expr} \rangle ::= \langle \text{Expr} \rangle + \langle \text{Term} \rangle \mid \langle \text{Expr} \rangle - \langle \text{Term} \rangle \mid \text{Term}$
 - $\langle \text{Term} \rangle ::= \langle \text{Term} \rangle * \langle \text{Factor} \rangle \mid \langle \text{Term} \rangle / \langle \text{Factor} \rangle \mid \langle \text{Term} \rangle \% \langle \text{Factor} \rangle \mid \langle \text{Factor} \rangle$
 - $\langle \text{Factor} \rangle ::= \langle \text{Primary} \rangle ** \langle \text{Factor} \rangle \mid \langle \text{Primary} \rangle$
 - $\langle \text{Primary} \rangle ::= 0 \mid 1 \mid \dots \mid 9$

Precedence	Associativity	Operators
3	right	**
2	left	* / %
1	left	+ -

These relationships are shown by the structure of the parse tree — highest precedence at the bottom, and left-associativity on the left at each level

Parse Tree of $4^{**}2^{**}3+5*6+7$

- An grammar is *ambiguous* if one of its strings has two or more different parse trees
- An ambiguous grammar G_2 :
 - $\langle \text{Expr} \rangle ::= \langle \text{Expr} \rangle \text{ op } \langle \text{Expr} \rangle \mid (\text{Expr}) \mid \text{Integer}$
 - $\langle \text{op} \rangle ::= + \mid - \mid / \mid \% \mid **$
- G_2 is equivalent to G_1 , i.e., both languages are same
- G_2 has fewer productions and nonterminals than G_1
- G_2 is ambiguous

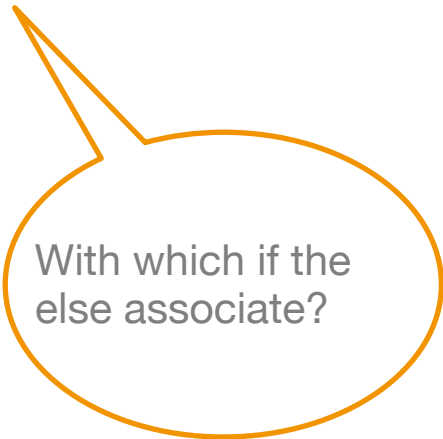

-
- The image displays two parse trees for the expression $(5 - 4) + 3$, illustrating different operator precedence interpretations.
- Left Tree (Correct Precedence):** This tree represents the expression $(5 - 4) + 3$. The root node is **Expr**, which branches into **Expr**, **op** (+), and **Expr** (3). The left **Expr** node branches into **Expr**, **op** (-), and **Expr** (4). The leftmost **Expr** node branches into the terminal value 5.
- Right Tree (Incorrect Precedence):** This tree represents the expression $5 - (4 + 3)$. The root node is **Expr**, which branches into **Expr** (5), **op** (-), and **Expr**. The right **Expr** node branches into **Expr**, **op** (+), and **Expr** (3). The left **Expr** node branches into the terminal value 4.

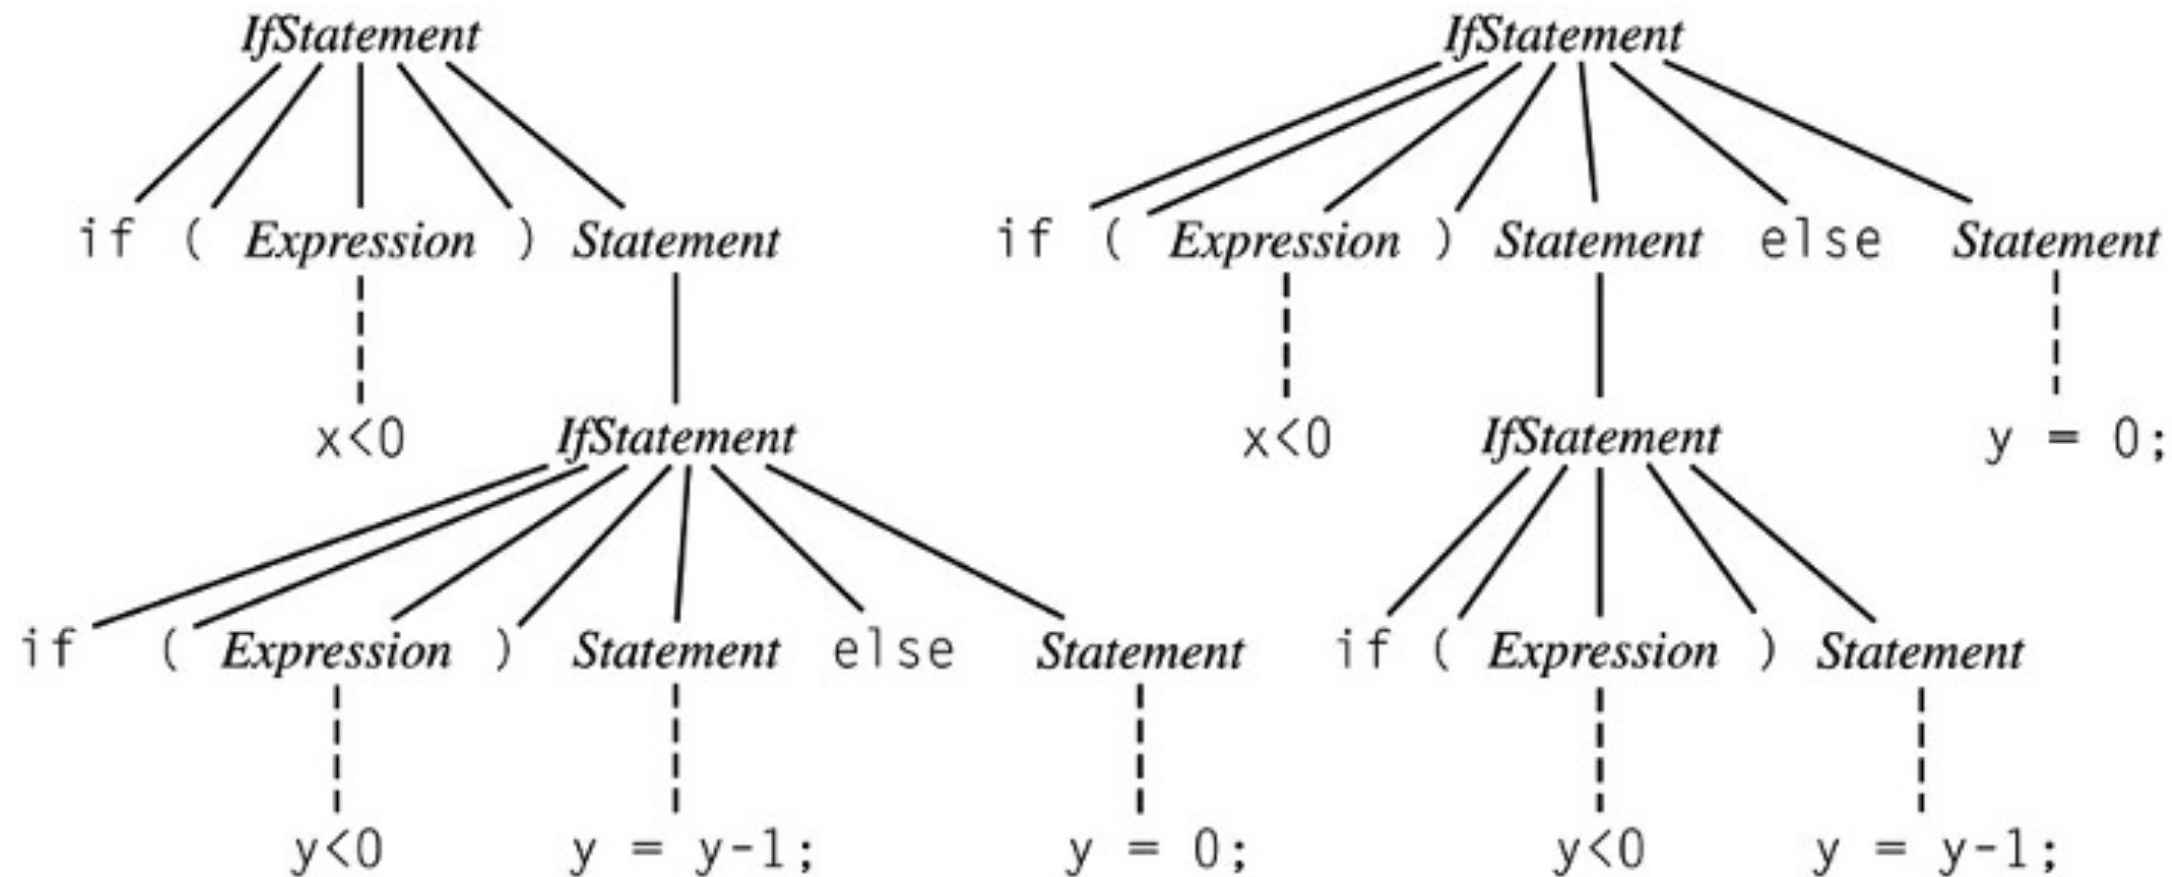

- $\langle \text{IfStatement} \rangle ::= \langle \text{if (Expression)} \rangle \langle \text{Statement} \rangle \mid \langle \text{if (Expression)} \rangle \langle \text{Statement} \rangle \langle \text{else} \rangle \langle \text{Statement} \rangle$
- $\langle \text{Statement} \rangle ::= \langle \text{Assignment} \rangle \mid \langle \text{IfStatement} \rangle \mid \langle \text{Block} \rangle$
- $\langle \text{Block} \rangle ::= \langle \{ \rangle \langle \text{Statement} \rangle \langle \} \rangle$
- $\langle \text{Statement} \rangle ::= \langle \text{Statement} \rangle \mid \langle \text{Statement} \rangle \langle \text{Statement} \rangle$

```
if(x < 0)
  if(y < 0) y = y - 1;
  else y = 0;
```

An orange speech bubble with a tail pointing towards the 'else' statement in the code above.

With which if the
else associate?

```
if(x < 0)
  if(y < 0) y = y - 1;
  else y = 0;
```

Can associate with
any if

- Algol 60, C, C++:
 - associate each else with the closest if
 - use {} or begin ... end to override
- Algol 68, Modula, Ada:
 - use explicit delimiter to end every conditional
 - e.g., if ... fi
- Java: rewrite the grammar to limit what can appear in a conditional:
 - $\langle \text{IfThenStatement} \rangle ::= \langle \text{if} \rangle \langle (\text{Expression}) \rangle \langle \text{Statement} \rangle$
 - $\langle \text{IfThenElseStatement} \rangle ::= \langle \text{if} \rangle \langle (\text{Expression}) \rangle \langle \text{StatementNoShortIf} \rangle \langle \text{else} \rangle \langle \text{Statement} \rangle$
 - The category $\langle \text{StatementNoShortIf} \rangle$ includes all statements except $\langle \text{IfThenStatement} \rangle$

- Programming Languages: Principles and Paradigms by Allen B. Tucker and Robert E. Noonan
